Case report

A glass marble ball in the maxillary sinus, transorbital floor penetration: A case report

Krissanaporn Jirawarakul*

Yala Hospital, Mueang Yala, Yala, Thailand

Foreign bodies in the sinus are uncommon and transorbital foreign bodies in the maxillary sinus are very rare. We hereby described a case of a glass marble ball about 1.6 cm in diameter that penetrated into the right maxillary sinus through the orbital floor without globe rupture. The foreign body in the sinus should be removed to prevent further infection and other complications. In this case, the glass marble ball was removed by a transnasal endoscopic technique with a widened maxillary antrum after guarding of orbital ball upward in order to prevent the orbital injury. There were no immediate and long term postoperative complications.

Keywords: Foreign body, transorbital, maxillary sinus.

The presence of foreign bodies in the maxillary sinus is uncommon. Most foreign bodies are of dental origin such as teeth.⁽¹⁾ Transorbital maxillary sinus foreign bodies are rare. For removal of a foreign body in the maxillary sinus, there are two main surgical approaches: external and endoscopic sinus surgery. We describe an unusual case of a glass marble ball that penetrated into the maxillary sinus through the orbital floor. The presentation of the patient and the surgical technique are hereby described.

Case report

A 13-year-old male patient visited the hospital for an injury on his right eye. The right eye was hit by a glass marble ball. The patient was admitted by an ophthalmologist. He was diagnosed as orbital trauma with severe chemosis without globe ruptured and received supportive treatment with local eye care and pain killers for two days. The examination revealed swelling of upper and lower eyelid with total hyphema and marked chemosis of the right eye (Figure 1). His right eye vision was light perception. The pain of his right eye and cheek still persisted; therefore, a skull

X-ray was performed to evaluate the extent of eye injury (Figure 2). The round shaped foreign body was found in the right maxillary sinus. Then, otolaryngologist was consulted for foreign body removal. The additional examination by the otolaryngologist revealed minimal bloody discharge from right middle meatus and swelling nasal mucosa from nasal endoscopy. A CT scan of the paranasal sinuses showed a round shaped foreign body about 1.6 cm in diameter and fracture at the floor of right orbit. Swelling of the right optic nerve was also noted (Figure 3).

Removal of the glass marble ball from the right maxillary sinus was performed under general anesthesia via a transnasal endoscopic technique. Uncinectomy was done and the maxillary ostium was widened using a microdebrider. The bone of the orbital floor was broken and had fallen to obstruct the maxillary antrum. A right subciliary incision was done and then the right eyeball was retracted the upward (Figure 4). The size of defect of the orbital floor was 1.63 cm. The glass marble ball was removed via the widened maxillary antrum using the aid of a curved suction. The orbital floor defect was reconstructed using titanium mesh.

Postoperatively, the patient was treated with antibiotics and eye care. A nasal endoscopic examination was performed one week after the operation. The visual acuity turned to no light perception. The chemosis was resolved within two weeks. There was no immediate and long term complications from the surgical removal.

Figure 1. Patient with his right chemosis.

Figure 2. X-ray of skull anteroposterior view (A) and lateral view (B): a round radiopaque foreign body in the right maxillary sinus.

Figure 3. Coronal section of CT scan: a 1.6 cm round shape foreign body in the right maxillary sinus with fracture of the right orbital floor.

Figure 4. Subciliary approach showed orbital floor defect (A) and the glass marble ball after removal (B).

Discussion

Foreign bodies in the maxillary sinus are uncommon. Transorbital maxillary sinus foreign bodies are very rare. There have been few cases reported. First was a 30-year-old male patient with a broken handle of scooter lodged in the right maxillary sinus.⁽²⁾ It penetrated through the orbital floor without any injury to the globe and it was removed via a buccal sulcus approach. The second case was a 60-year-old male patient with a broken pen, 20 years after trauma, lodged in the left maxillary sinus causing ectropion of left lower eyelid.⁽³⁾ The pen was removed via subciliary incision.

In this case report, a glass marble ball with a size of 1.6 cm in diameter was found on a skull X-ray at the floor of maxillary sinus. A screening CT scan of the paranasal sinuses provided the extent of the injury and the anatomical defects from the injury. The choices for removal a foreign body in the maxillary sinus are open surgery via a Caldwell Luc approach and functional endoscopic sinus surgery or a combination.⁽⁴⁾ Nowadays, the most common procedure is a functional endoscopic approach.^(5, 6) The advantages of an endoscopic approach include its less invasive, a short recovery time and decreased risk of infraorbital nerve injury.⁽⁷⁾

We found that the fractured floor orbit and the orbital fat had fallen to obstruct the maxillary ostium. Therefore, we could not access through the middle meatal antrostomy. We had to combine the open approach via a subciliary incision with a nasal endoscopic approach for the removal of the glass

marble ball. Guarding of the orbital ball should be performed before a maxillary approach in order to prevent orbital injury.

Even if the glass marble ball could be removed via the defected site at orbital floor, we desired to widen the maxillary ostium in order to prevent osteomeatal complex (OMU) obstruction from the fallen orbital floor. Another advantage of the maxillary antrostomy is post-operative sinus drainage care.

This case is interesting because of the route of entry of the foreign body. Then, the foreign body was removed via endoscopic sinus surgery.

Conclusion

A non-dental origin foreign body in the maxillary sinus is uncommon. The foreign body in the sinus should be removed to prevent further infection and other complications. CT scans of paranasal sinuses should be performed for surgical planning. Nowadays, an endoscopic approach is the first line of surgical approach. An open approach is necessary in some cases such as a very large foreign body or a fallen orbit obstructs the natural opening of the sinus.
